Insights on the future of cosmetic care.

CHANGING EYE COLOR

“This is a really exciting new topic...Their technology (Strōma Medical) is non-ablative. It uses a green light laser to repeatedly heat the anterior surface of the iris to the point that instead of bleeding pigment into the eye, macrophages come in and clear the pigment through the circulatory system. It’s about a three-week process. And because underneath every brown eye, there’s actually a grey stroma, and this is what actually appears blue when you look at a person’s eye who has blue eyes.”

—Julie Woodward, MD
